# Public Key Cryptography and the RSA Algorithm

Cryptography and Network Security

by William Stallings

Lecture slides by Lawrie Brown

Edited by Dick Steflik

# Private-Key Cryptography

- traditional **private/secret/single key** cryptography uses **one** key
- Key is shared by both sender and receiver
- if the key is disclosed communications are compromised
- also known as **symmetric**, both parties are equal
  - hence does not protect sender from receiver forging a message & claiming is sent by sender

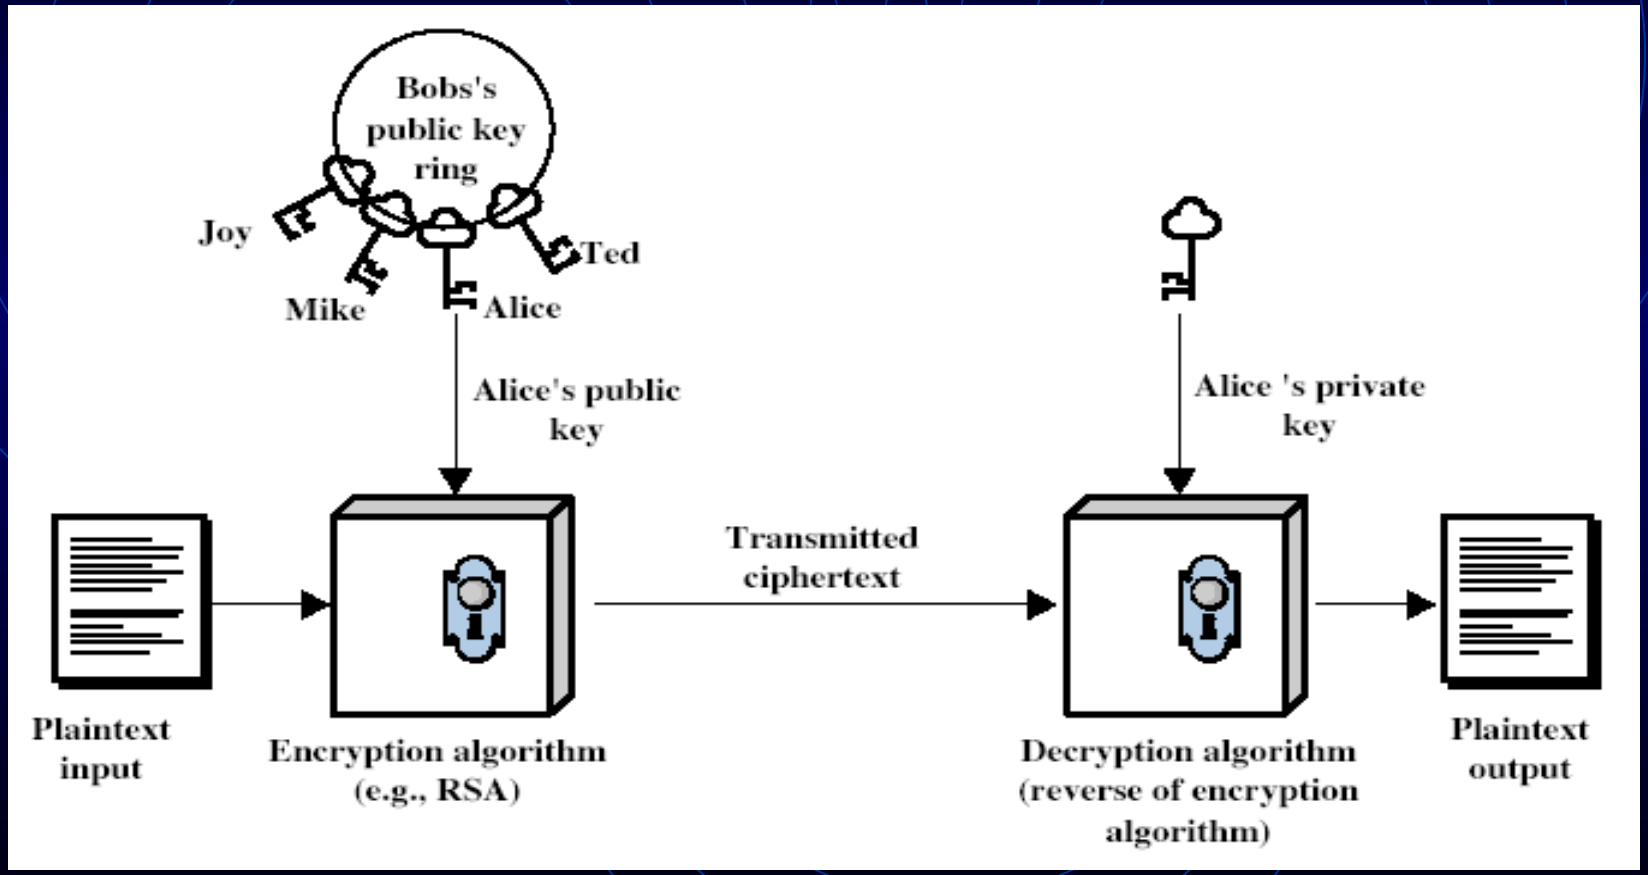
# Public-Key Cryptography

- probably most significant advance in the 3000 year history of cryptography
- uses **two** keys – a public key and a private key
- **asymmetric** since parties are **not** equal
- uses clever application of number theory concepts to function
- complements **rather than** replaces private key cryptography

# Public-Key Cryptography

- **public-key/two-key/asymmetric** cryptography involves the use of **two** keys:
  - a **public-key**, which may be known by anybody, and can be used to **encrypt messages**, and **verify signatures**
  - a **private-key**, known only to the recipient, used to **decrypt messages**, and **sign** (create) **signatures**
- is **asymmetric** because
  - those who encrypt messages or verify signatures **cannot** decrypt messages or create signatures

# Public-Key Cryptography



# Why Public-Key Cryptography?

- developed to address two key issues:
  - **key distribution** – how to have secure communications in general without having to trust a KDC with your key
  - **digital signatures** – how to verify a message comes intact from the claimed sender
- public invention due to Whitfield Diffie & Martin Hellman at Stanford U. in 1976
  - known earlier in classified community

# Public-Key Characteristics

- Public-Key algorithms rely on two keys with the characteristics that it is:
  - computationally infeasible to find decryption key knowing only algorithm & encryption key
  - computationally easy to en/decrypt messages when the relevant (en/decrypt) key is known
  - either of the two related keys can be used for encryption, with the other used for decryption (in some schemes)

# Public-Key Cryptosystems

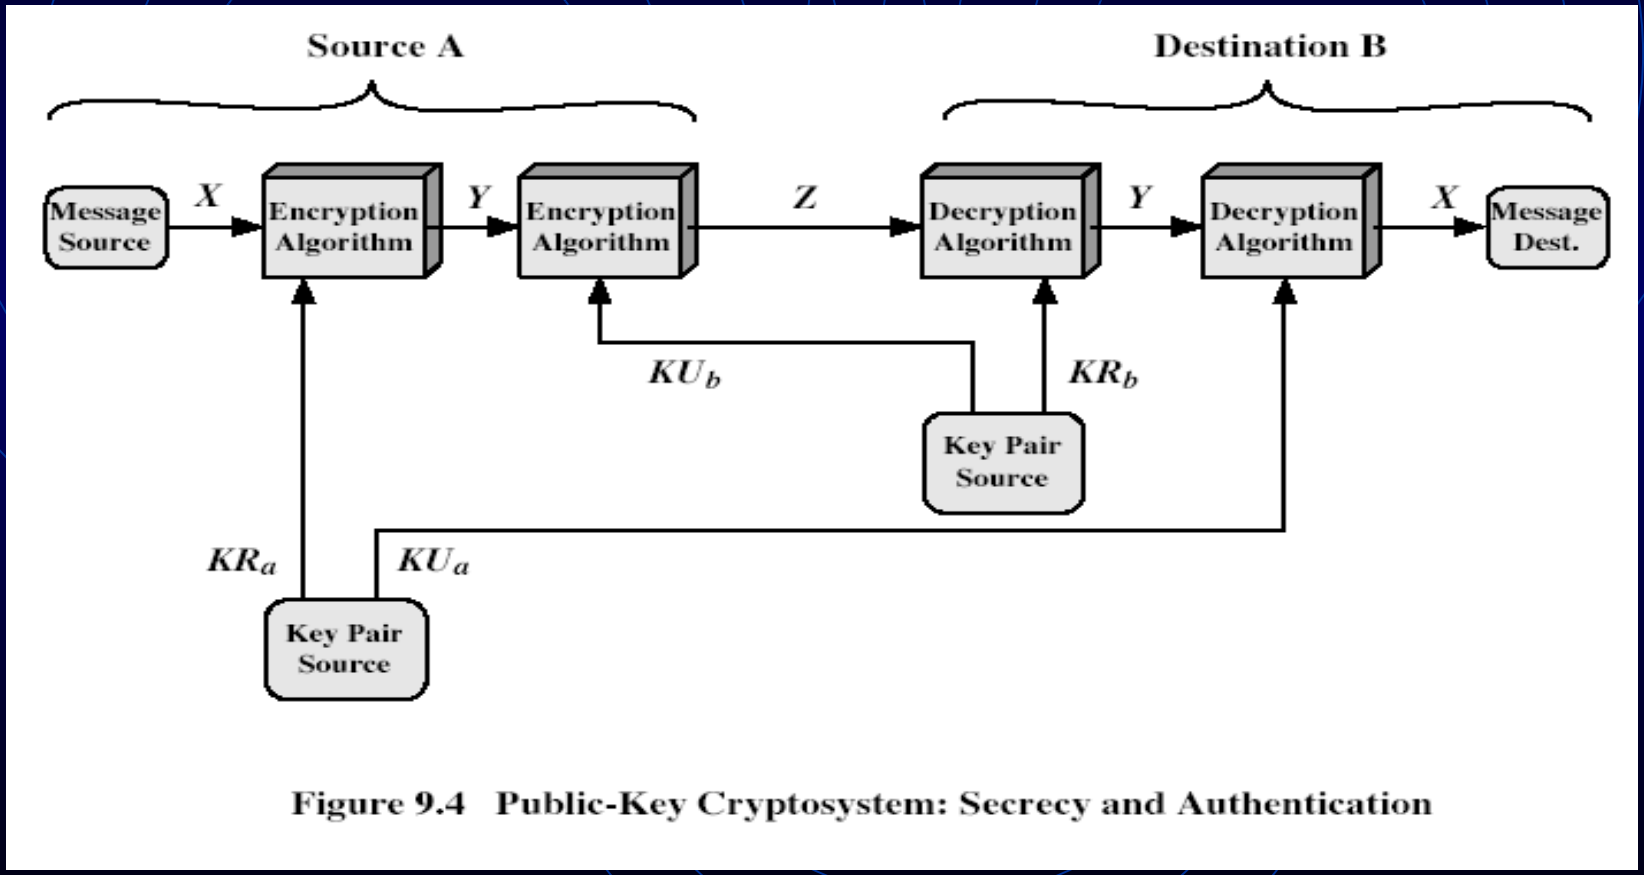


Figure 9.4 Public-Key Cryptosystem: Secrecy and Authentication

# Public-Key Applications

- can classify uses into 3 categories:
  - **encryption/decryption** (provide secrecy)
  - **digital signatures** (provide authentication)
  - **key exchange** (of session keys)
- some algorithms are suitable for all uses, others are specific to one

# Security of Public Key Schemes

- like private key schemes brute force **exhaustive search** attack is always theoretically possible
- but keys used are too large (>512bits)
- security relies on a **large enough** difference in difficulty between **easy** (en/decrypt) and **hard** (cryptanalyse) problems
- more generally the **hard** problem is known, its just made too hard to do in practise
- requires the use of **very large numbers**
- hence is **slow** compared to private key schemes

# RSA

- by Rivest, Shamir & Adleman of MIT in 1977
- best known & widely used public-key scheme
- based on exponentiation in a finite (Galois) field over integers modulo a prime
  - nb. exponentiation takes $O((\log n)^3)$ operations (easy)
- uses large integers (eg. 1024 bits)
- security due to cost of factoring large numbers
  - nb. factorization takes $O(e^{\log n \log \log n})$ operations (hard)

# The Maths Behind RSA

- Prime generation is easy: It's easy to find a random prime number of a given size.
  - Generate random numbers of a given size
  - Apply Primality tests to test whether the number is prime
  - Like Fermat's little Theorem
    - if p is prime and a is not divisible by p, then

$$a^{p-1} \equiv 1 \ (mod\ p)$$

# The Maths Behind RSA

- Multiplication of 2 given numbers $p$ and $q$ is easy.
  - Karatsuba's Algorithm
  - $XY = \left(X_1 2^{\frac{n}{2}} + X_r\right)\left(Y_1 2^{\frac{n}{2}} + Y_r\right) = 2^n X_1 Y_1 + 2^{\frac{n}{2}}(X_1 Y_r + X_r Y_1) + X_r Y_r$
  - $X_1 Y_r + X_r Y_1 = (X_1 + X_r)(Y_1 + Y_r) - X_1 Y_1 - X_r Y_r$

# The Maths Behind RSA

- Factoring is hard: Given an $n=pq$, it appears to be quite hard to recover the prime factors $p$ and $q$.
- Modular exponentiation is easy: Given $n$, $m$, and $e$, it's easy to compute $c = m^e \bmod n$.

# RSA Key Setup

- each user generates a public/private key pair by:
- selecting two large primes at random - $p$, $q$
- computing their system modulus $N=p.q$
  - note $\varnothing(N)=(p-1)(q-1)$
- selecting at random the encryption key $e$
  - where $1<e<\varnothing(N)$, $\gcd(e,\varnothing(N))=1$
- solve following equation to find decryption key $d$
  - $e.d=1 \mod \varnothing(N)$ and $0 \leq d \leq N$
- publish their public encryption key: KU={e,N}
- keep secret private decryption key: KR={d,p,q}

# RSA Use

- to encrypt a message M the sender:
  - obtains **public key** of recipient $KU=\{e,N\}$
  - computes: $C=M^e \bmod N$, where $0 \leq M < N$
- to decrypt the ciphertext C the owner:
  - uses their private key $KR=\{d,p,q\}$
  - computes: $M=C^d \bmod N$
- note that the message M must be smaller than the modulus N (block if needed)

# Why RSA Works

- because of Euler's Theorem:
- $a^{\phi(n)} \bmod N = 1$
  - where $\gcd(a,N)=1$
- in RSA have:
  - $N=p.q$
  - $\phi(N)=(p-1)(q-1)$
  - carefully chosen e & d to be inverses $\bmod \phi(N)$
  - hence $e.d=1+k.\phi(N)$ for some k
- hence :

$$C^d = (M^e)^d = M^{1+k.\phi(N)} = M^1.(M^{\phi(N)})^q = M^1.(1)^q = M^1 = M \bmod N$$

# RSA Example

1. Select primes: $p=17$ & $q=11$
2. Compute $n = pq = 17 \times 11 = 187$
3. Compute $\phi(n) = (p-1)(q-1) = 16 \times 10 = 160$
4. Select $e$ : $\gcd(e,160)=1$; choose $e=7$
5. Determine $d$: $de=1 \mod 160$ and $d < 160$
   Value is $d=23$ since $23 \times 7 = 161 = 10 \times 160 + 1$
6. Publish public key $KU=\{7,187\}$
7. Keep secret private key $KR=\{23,17,11\}$

# RSA Example cont

- sample RSA encryption/decryption is:
- given message $M = 88$ (nb. $88<187$)
- encryption:

  $C = 88^7 \bmod 187 = 11$
- decryption:

  $M = 11^{23} \bmod 187 = 88$

# Exponentiation

- can use the Square and Multiply Algorithm
- a fast, efficient algorithm for exponentiation
- concept is based on repeatedly squaring base
- and multiplying in the ones that are needed to compute the result
- look at binary representation of exponent
- only takes $O(\log_2 n)$ multiples for number n
  - eg. $7^5 = 7^4 . 7^1 = 3 . 7 = 10 \mod 11$
  - eg. $3^{129} = 3^{128} . 3^1 = 5 . 3 = 4 \mod 11$

# Exponentiation

```
c ← 0; d ← 1
for i ← k downto 0
        do   c ← 2 × c
             d ← (d × d) mod n
             if   b_i = 1
                  then   c ← c + 1
                         d ← (d × a) mod n
return d
```

# RSA Key Generation

- users of RSA must:
  - determine two primes at random - `p, q`
  - select either `e` or `d` and compute the other
- primes `p,q` must not be easily derived from modulus `N=p.q`
  - means must be sufficiently large
  - typically guess and use probabilistic test
- exponents `e, d` are inverses, so use Inverse algorithm to compute the other

# RSA Security

- three approaches to attacking RSA:
  - brute force key search (infeasible given size of numbers)
  - mathematical attacks (based on difficulty of computing ø(N), by factoring modulus N)
  - timing attacks (on running of decryption)

# Factoring Problem

- mathematical approach takes 3 forms:
  - factor N=p.q, hence find ø(N) and then d
  - determine ø(N) directly and find d
  - find d directly
- currently believe all equivalent to factoring
  - have seen slow improvements over the years
    - as of Aug-99 best is 130 decimal digits (512) bit with GNFS
  - biggest improvement comes from improved algorithm
    - cf "Quadratic Sieve" to "Generalized Number Field Sieve"
  - barring dramatic breakthrough 1024+ bit RSA secure
    - ensure p, q of similar size and matching other constraints

# Timing Attacks

- developed in mid-1990's
- exploit timing variations in operations
  - eg. multiplying by small vs large number
  - or IF's varying which instructions executed
- infer operand size based on time taken
- RSA exploits time taken in exponentiation
- countermeasures
  - use constant exponentiation time
  - add random delays
  - blind values used in calculations

# Summary

- have considered:
  - principles of public-key cryptography
  - RSA algorithm, implementation, security
