# **Password Security**

#### **Access Control**

- Two parts to access control...
- Authentication: Are you who you say you are?
  - Determine whether access is allowed or not
  - Authenticate human to machine
  - Or, possibly, machine to machine
- Authorization: Are you allowed to do that?
  - Once you have access, what can you do?
  - Enforces limits on actions
- Note: "access control" often used as synonym for authorization

### Are You Who You Say You Are?

- Authenticate a human to a machine?
- Can be based on...
  - Something you know
    - For example, a password
  - Something you have
    - For example, a smartcard
  - Something you are
    - For example, your fingerprint

#### Something You Know

- Passwords
- Lots of things act as passwords!
  - PIN
  - Social security number
  - Mother's maiden name
  - Date of birth
  - Name of your pet, etc.

#### Trouble with Passwords

- "Passwords are one of the biggest practical problems facing security engineers today."
- "Humans are incapable of securely storing highquality cryptographic keys, and they have unacceptable speed and accuracy when performing cryptographic operations."

# Why Passwords?

- Why is "something you know" more popular than "something you have" and "something you are"?
- Cost: passwords are free
- Convenience: easier for sysadmin to reset pwd than to issue a new thumb

### Keys vs Passwords

- Crypto keys
- Suppose key is 64 bits
- Then 2<sup>64</sup> keys
- Choose key at random...
- ...then attacker must try about 2<sup>63</sup> keys

- Passwords
- Suppose passwords are 8 characters, and 256 different characters
- Then  $256^8 = 2^{64}$  pwds
- Users do not select passwords at random
- Attacker has far less than 2<sup>63</sup> pwds to try (dictionary attack)

#### Good and Bad Passwords

- Bad passwords
  - frank
  - Fido
  - Password
  - incorrect
  - Pikachu
  - -102560
  - AustinStamp

- Good Passwords?
  - jflej,43j-EmmL+y
  - -09864376537263
  - P0kem0N
  - FSa7Yago
  - OnceuPOnAt1m8
  - PokeGCTall150

#### Password Experiment

- Three groups of users each group advised to select passwords as follows
  - Group A: At least 6 chars, 1 non-letter
- winner → Group B: Password based on passphrase
  - Group C: 8 random characters
  - Results
    - Group A: About 30% of pwds easy to crack
    - Group B: About 10% cracked
      - Passwords easy to remember
    - Group C: About 10% cracked
      - Passwords hard to remember

#### Password Experiment

- User compliance hard to achieve
- In each case, 1/3rd did not comply
  - And about 1/3rd of those easy to crack!
- Assigned passwords sometimes best
- If passwords not assigned, best advice is...
  - Choose passwords based on passphrase
  - Use pwd cracking tool to test for weak pwds
- Require periodic password changes?

#### Attacks on Passwords

- Attacker could...
  - Target one particular account
  - Target any account on system
  - Target any account on any system
  - Attempt denial of service (DoS) attack
- Common attack path
  - Outsider  $\rightarrow$  normal user  $\rightarrow$  administrator
  - May only require one weak password!

#### Password Retry

- Suppose system locks after 3 bad passwords.
   How long should it lock?
  - 5 seconds
  - 5 minutes
  - Until SA restores service
- What are +'s and -'s of each?

#### Password File?

- Bad idea to store passwords in a file
- But we need to verify passwords
- Solution? Hash passwords
  - Store y = h(password)
  - Can verify entered password by hashing

- If Trudy obtains the password file, she does not (directly) obtain passwords
- But Trudy can try a forward search
  - Guess x and check whether y = h(x)

#### **Dictionary Attack**

- Trudy pre-computes h(x) for all x in a dictionary of common passwords
- Suppose Trudy gets access to password file containing hashed passwords
  - She only needs to compare hashes to her precomputed dictionary
  - After one-time work of computing hashes in dictionary, actual attack is trivial
- Can we prevent this forward search attack? Or at least make it more difficult?

#### Salt

- Hash password with salt
- Choose random salt s and compute
   y = h(password, s)
   and store (s,y) in the password file
- Note that the salt S is not secret
- Still easy to verify salted password
- But lots more work for Trudy
  - Why?

# Password Cracking: Do the Math

- Assumptions:
- Pwds are 8 chars, 128 choices per character
  - Then  $128^8 = 2^{56}$  possible passwords
- There is a password file with 2<sup>10</sup> pwds
- Attacker has dictionary of 2<sup>20</sup> common pwds
- Probability 1/4 that password is in dictionary
- Work is measured by number of hashes

### Password Cracking: Case I

- Attack 1: specific password without using a dictionary
  - E.g., Alice's password
  - Must try  $2^{56}/2 = 2^{55}$  on average
  - Like exhaustive key search
- Does salt help in this case?

#### Password Cracking: Case II

- Attack 1 specific password with dictionary
- With salt
  - Expected work:  $1/4 (2^{19}) + 3/4 (2^{55}) \approx 2^{54.6}$
  - In practice, try all pwds in dictionary...
  - ...then work is at most  $2^{20}$  and probability of success is 1/4
- What if no salt is used?
  - One-time work to compute dictionary:  $2^{20}$
  - Expected work is of same order as above

### Password Cracking: Case III

- Attack3: Any of 1024 pwds in file, without dictionary
  - Assume all 2<sup>10</sup> passwords are distinct
  - Need 2<sup>55</sup> comparisons before expect to find pwd
- If no salt is used
  - Each computed hash yields 2<sup>10</sup> comparisons
  - So expected work (hashes) is  $2^{55}/2^{10} = 2^{45}$
- If salt is used
  - Expected work is 2<sup>55</sup>
  - Each comparison requires a hash computation

#### Password Cracking Tools

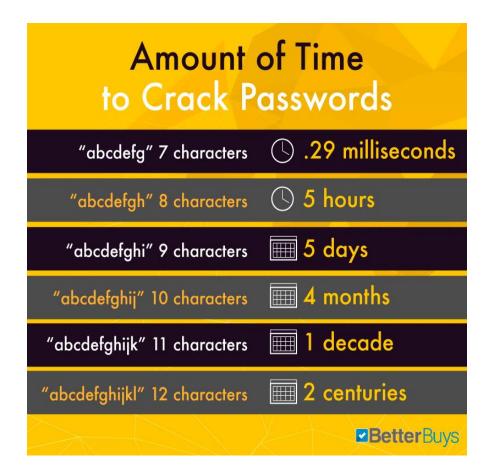

- Popular password cracking tools
  - Password Crackers
    - http://www.pwcrack.com/index.shtml
  - Password Portal
    - http://www.passwordportal.net/
  - L0phtCrack and LC4 (Windows)
    - http://www.atstake.com/products/lc/
  - John the Ripper (Unix)
    - http://www.openwall.com/john/
- Admins should use these tools to test for weak passwords since attackers will
- Good articles on password cracking

  - Passwords revealed by sweet deal
    - http://news.bbc.co.uk/2/hi/technology/3639679.stm

#### Test a New Password

# Password Cracking

- Initially for password cracking, brute force attack was conducted
- However, the time complexity of cracking passwords of a reasonably large length is quite high
- Now the availability of password cracking algorithms have reduced this high time requirement

#### Some Interesting Facts

- Password files of many giant web-based organizations have been compromised
  - Adobe (150 million)
  - Evernote (50 million)
  - Anthem (40 million)
  - RockYou (32 million)
  - Tianya (28 million)
  - Dodonew (16 million)
  - Gmail (4.9 million)

- Interestingly, some of the breaches came into notice after a long time of the actual leakage
  - Yahoo: leakage 2013 and revealed in 2017
  - Dropbox: between leakage and revealed 4 years
  - Myspace: between leakage and revealed 8 years

**—** ...

**Detection of timely password breach is important** 

# How to detect password breach?

#### Honeywords: Making Password-Cracking Detectable

Ari Juels RSA Laboratories Cambridge, MA, USA ari.juels@rsa.com Ronald L. Rivest MIT CSAIL Cambridge, MA, USA rivest@mit.edu

#### ABSTRACT

We propose a simple method for improving the security of hashed passwords: the maintenance of additional "honeywords" (false passwords) associated with each user's account. An adversary who steals a file of hashed passwords and inverts the hash function cannot tell if he has found the password or a honeyword. The attempted use of a honeyword for login sets off an alarm. An auxiliary server (the "honeychecker") can distinguish the user password from honeywords for the login routine, and will set off an alarm if a honeyword is submitted. Times [32]. The past year has also seen numerous highprofile thefts of files containing consumers' passwords; the hashed passwords of Evernote's 50 million users were exposed [20] as were those of users at Yahoo, LinkedIn, and eHarmony, among others [19].

One approach to improving the situation is to make password hashing more complex and time-consuming. This is the idea behind the "Password Hashing Competition." This approach can help, but also slows down the authentication process for legitimate users, and doesn't make successful password cracking easier to detect.

Sometimes administrators set up fake user accounts ("hon-

#### **ACM CCS 2013**

#### Assumption

- The paper assumes a computer system with n users
- u<sub>1</sub>, u<sub>2</sub>, ..., u<sub>n</sub>
- p<sub>i</sub> denotes the password of ith user u<sub>i</sub>
- This p<sub>i</sub> is the legitimate password that user uses for login purpose
- Traditional systems store
  - Unsalted: (u<sub>i</sub>,H(p<sub>i</sub>)) or Salted: (u<sub>i</sub>,H(p<sub>i</sub>,s<sub>i</sub>))

#### To setup the honeyword based system

- For each user u<sub>i</sub>, a list W<sub>i</sub> of distinct words (called "potential passwords" or more briefly, "sweetwords") is represented: W<sub>i</sub> = (w<sub>i</sub>,1, w<sub>i</sub>,2,..., w<sub>i</sub>,k)
- The list W<sub>i</sub> of sweetwords thus contains one sugarword (the password) and (k 1) honeywords (the chaff)
- An auxiliary secure server, called the "honeychecker", is used to store the index of the sugarword

- The system login routine needs to determine whether a proffered password g is
  - user's password or not
  - a honeyword or not
  - anything other than password or honeywords
- If the adversary has entered one of the user's honeywords,
  - then an appropriate action takes place (determined by policy)

- When user u<sub>i</sub> changes her password, or sets it up when her account is first initialized, procedure Gen(k) is used to obtain
  - a new list W<sub>i</sub> of k sweetwords,
  - the list H<sub>i</sub> of their hashes, and
  - the value c(i) of the index of the correct password  $p_i$  in  $W_i$
- Then, securely notify the honeychecker of the new value of c(i), and update the user's entry in the file F to (u<sub>i</sub>, H<sub>i</sub>)

#### **Honeyword Generation**

- Based on the impact on the user interface (UI) for password change
  - With legacy-UI procedures
    - the password-change UI is unchanged.
  - With modified-UI procedures
    - the password-change UI is modified to allow for better password/honeyword generation.

# Legacy-UI password changes

- With a legacy-UI method,
  - the password-change procedure asks the user for the new password
  - The UI does not tell the user about the use of honeywords, nor interact with her to influence her password choice

Honeyword generation procedure can be changed without needing to notify anyone or to change the UI

#### Honeyword Generation

- We start with a password p<sub>i</sub> supplied by user
   u<sub>i</sub>
- The system then generates a set of k-1
  honeywords "similar in style" to the password
  p<sub>i</sub>, or at least plausible as legitimate
  passwords, so that an adversary will have
  difficulty in identifying p<sub>i</sub> in the list W<sub>i</sub> of all
  sweetwords for user u<sub>i</sub>

# Chaffing

- The password p<sub>i</sub> is picked, and then the honeyword generation procedure Gen(k, p<sub>i</sub>) or "chaff procedure" generates a set of k 1 additional distinct honeywords ("chaff").
- Note that the honeywords may depend upon the password p<sub>i</sub>
- The password and the honeywords are placed into a list W<sub>i</sub>, in random order
- The value c(i) is set equal to the index of p<sub>i</sub> in this list

# Chaffing by tweaking

- "tweak" selected character positions of the password to obtain the honeywords
- Let t denotes the desired number of positions to tweak (such as t = 2 or t = 3).
  - If password is "BG+7y45", then the list  $W_i$  might be (for tail-tweaking with t = 3 and k = 4):
  - BG+7q03, BG+7m55, BG+7y45, BG+7o92
- Another example
  - chaffing-by tweaking-digits for t = 2:
  - 42\*flavors, 57\*flavors, 18\*flavors

# Chaffing-with-a-password-model

- Generates honeywords using a probabilistic model of real passwords
- Unlike the previous chaffing methods, this method does not necessarily need the password in order to generate the honeywords, and it can generate honeywords of widely varying strength

# An Example of 19 generated honeywords

#### **Modeling Syntax**

- [Bojinov et al., ESORICS 2010] propose an interesting approach based on the work of [Weir et al., IEEE SP, 2009] to chaffing-with-apasswordmodel in which honeywords are generated using the same syntax as the password
- Here, honeywords do depend on the password

#### **Modeling Syntax**

- The password is parsed into a sequence of "tokens," each representing a distinct syntactic element—a word, number, or set of special characters
  - For example, the password mice3blind might be decomposed into the token sequence W4 | D1
     |W5
  - meaning a 4-letter word followed by a 1-digit number and then a 5-letter word

- Honeywords are then generated by replacing tokens with randomly selected values that match
  - For example, the choice W4 ← "gold," D1 ← '5",
     W5 ← "rings" would yield the honeyword gold5rings
  - Replacements for word tokens are selected from a dictionary provided as input to the generation algorithm

# Chaffing with "tough nuts"

- One might also like to have some honeywords that are much harder to crack than the average
- So, the adversary would not then (as we have been assuming) be faced with a completely broken list of sweetwords, but rather only a partial list
- There may possibly be some uncracked hashes (represented by '?' here) still to work on, with the correct password possibly among them

# Chaffing with "tough nuts"

 For example, what should the adversary do with the following list?

```
gt79, tom@yahoo, ?, g*7rn45, rabid/30frogs!, ?
```

- Having some "tough nuts" among the honeywords might give the adversary additional reason to pause before diving in and trying to log in with one of the cracked ones
- "Tough nuts" represent potentially correct passwords whose plausibility the adversary cannot evaluate

#### Modified UI Password Changes

- Take-a-tail
- Utilizes a modified UI for password changes
- Similar to chaffing by tail tweaking method
- Except that the tail is now randomly chosen by the system

That is, the password-change UI is changed from:

Enter a new password:

to something like:

```
Propose a password: •••••

Append '413' to make your new password.

Enter your new password: •••••••
```

Password: RedEye2

New Password: RedEye2413

Honeywords can now be generated using chaffing by tail tweaking method

#### Other ways of generating honeywords

- Random pick honeyword generation
- A modified UI procedure
- Flat honeywords

- Generate a list W<sub>i</sub> of k distinct sweetwords in some arbitrary manner
  - May involve interaction with the users
- Also, pick randomly an element of this as the password
- The other elements become honeywords

#### Random-Pick Honeyword Generation

User may supply following six sweetwords-

```
4Tniners all41&14all i8apickle sin(pi/2) \{1,2,3\} AB12:YZ90
```

System may say pick any one of them as password

#### Some Issues

- User will have to create k number of sweetwords
- Users may remember a sweetword and may mistakenly enter that as a password
- System may treat that as honeyword

It may be better if the sweetwords are generated algorithmically

# Achieving Flatness: Selecting the Honeywords from Existing User Passwords

Imran Erguler

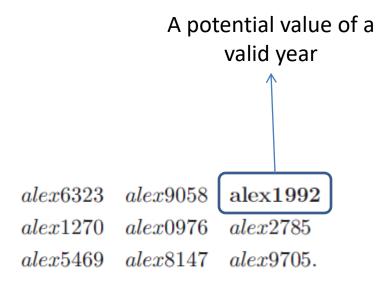

Abstract—Recently, Juels and Rivest proposed honeywords (decoy passwords) to detect attacks against hashed password databases. For each user account, the legitimate password is stored with several honeywords in order to sense impersonation. If honeywords are selected properly, a cyber-attacker who steals a file of hashed passwords cannot be sure if it is the real password or a honeyword for any account. Moreover, entering with a honeyword to login will trigger an alarm notifying the administrator about a password file breach. At the expense of increasing the storage requirement by 20 times, the authors introduce a simple and effective solution to the detection of password file disclosure events. In this study, we scrutinize the honeyword system and present some remarks to highlight possible weak points. Also, we suggest an alternative approach that selects the honeywords from existing user passwords in the system in order to provide realistic honeywords—a perfectly flat honeyword generation method—and also to reduce storage cost of the honeyword scheme.

Index Terms—Authentication, honeypot, honeywords, login, passwords, password cracking

47

#### Few Remarks by Erguler

- Remarks on Take-a-tail
  - "Although this method strengthens the password, to our point of view, it is impractical—some users even forget the passwords that they determined"
- Remarks on Chaffing-by-tweaking
  - "Many users have the propensity to choose the numbers included in passwords related to a special date, e.g. birthday, anniversary or an important historical event"

The digits in the honeywords don't make sense. Thus, alex1992 makes sense for an adversary

- Remarks on Chaffing-by-tweaking
  - Apart from the use of a date in passwords, many users prefer to append consecutive numbers to their password heads, like '123', '1234', due to the tendency of users to choose rememberable number patterns

A randomly replacing technique like this model leads an adversary to make a natural selection

- Remarks on Chaffing-with-a-Password-Model
  - Leaked password database shows that some of the passwords have a well known pattern

```
bond007 james007
007bond 007007.
```

 Even modeling syntax approach looses its effectiveness against such passwords

- Remarks on correlation
  - If there is a correlation between username and password then the password can be easily distinguishable
  - Example:
    - username/password-alice/alice123
    - username/password- peterparker/spiderman1992

- Remarks on tough-nuts
  - "an adversary may suppose that most of the passwords made up of simple words and digit combinations, not a tough nut. Hence, it is reasonable for this adversary to conduct her classic attack with skipping tough nuts contrarily to authors' expectations"

- Remarks on hybrid method
  - "... previous remarks are also valid for this case, e.g. in the above example an adversary may make plausible guesses"

```
\begin{array}{lll} happy9679 & apple 1422 & angel 2656 \\ happy 9757 & apple 1903 & angel 2036 \\ happy 9743 & apple 1172 & angel 2849 \\ happy 9392 & apple 1792 & angel 2562. \end{array}
```

- Remarks on DoS Attack
  - "the system limits for unsuccessful login attempts as n, i.e., after n consecutive wrong password trials the account will be blocked. Nonetheless, if the correct password is entered before n is reached, then system resets the wrong password counter"
  - "the adversary logins with the correct password at each nth attempt to avoid blocking of the account"

#### Two major issues

- Flatness of honeywords
  - The main purpose of honeywords will not serve
- Chance of hitting a honeyword
  - Leading to the DoS attack

#### Erguler's Proposal

- Use of existing passwords to stimulate the honeywords
- For each account k-1
   existing password
   indexes, which we call
   honeyindexes, are
   randomly assigned to a
   newly created account
   of u<sub>i</sub>, where k>=2
- A random index number is given to this account and hash of the correct password is kept with the correct index in a list
- In another list u<sub>i</sub> is stored with an integer set which is consisted of the honeyindexes and the correct index

## Erguler's Proposal

Username	Honeyindex Set
agent-lisa alexius baba13	$(93, 16, 626, \dots, 94, 931)  (15, 476, 51, 443, \dots, 88, 429)  (3, 62107, \dots, 91, 233)$
: zack_tayland zoom42	$ \begin{array}{c} \vdots\\ (1,009,23,471,\ldots,47,623)\\ (63,51234,\ldots,72,382) \end{array} $

Each username is paired with k numbers as sweetindexes and each of which points to real passwords in the system

## Two major advantages

- Less storage
- Achieving flatness

#### Initialization

- Firstly, T fake accounts (honeypots) are created with their passwords
- An unique index value between [1,N] is assigned to each created account randomly
- Then k-1 numbers are randomly selected from the index list for each account as honeyindex set
  - $-X_{i}=\{X_{i,1},X_{i,2},...,X_{i,k}\}$
  - One of the index of X<sub>i</sub> is the correct index

#### Initialization

- Two passwords files F1 and F2 are used in the main server
- F1 stores username and honeyindex set <hu<sub>i</sub>, X<sub>i</sub>>, here hu<sub>i</sub> denotes honeypot account
  - F1 is sorted alphabetically
- F2 keeps the index number and corresponding hash of the password <c<sub>i</sub>, H(p<sub>i</sub>)>
  - F2 is sorted according to the index values
  - Let S<sub>I</sub> denote the index column and S<sub>H</sub> represents the corresponding hash value

# Example

Let's create honeypot account <macbeth, master2014> An index number 1008 is assigned to it randomly

Hash of Password
:
H(master 2014)
÷

$S_I$	$S_H$
3	$H(p_3)$
7	$H(p_7)$
85	$H(p_{85})$
:	:
100,000	$H(p_{100000})$
100,004	$H(p_{100000})$ $H(p_{100004})$

- Then k-1 numbers are randomly chosen from S<sub>1</sub> of F<sub>2</sub>
- F1 is generated by combining with the correct index

Honeyindex Set
: :
(42, 96, 104, <b>1,008</b> , 7,201, 23,008)
<b>:</b>

#### Registration

- A legacy-UI is preferred
- The user as <u<sub>i</sub>, p<sub>i</sub>> registers to the system
- The honeyindex generator algorithm  $Gen(k,S_i) \rightarrow c_i, X_i$  which outputs  $c_i$  as the correct index for  $u_i$  and the honeyindexes  $X_i = \{x_{i,1}, x_{i,2}, ..., x_{i,k}\}$
- Gen(k,S<sub>I</sub>) produces X<sub>i</sub> randomly picking a number c<sub>i</sub> not in S<sub>I</sub>
- After c<sub>i</sub> and X<sub>i</sub> are obtained, <u<sub>i</sub>, c<sub>i</sub>> pair is delivered to the honeychecker

After the Registration Process, Change of  $F_2$  is Illustrated on the Left, while Update of  $F_1$  is Shown on the Right

$S_I$	$S_H$
3	$H(p_3)$
:	:
$c_i$	$H(p_i)$
:	:
:	:
100000	$H(p_{100000})$
100004	$H(p_{100004})$

Username	Honeyindex Set
agent-lisa	$(93, 16626, \ldots, 94931)$
alexius	$(15476, 51443, \ldots, 88429)$
baba13	$(3,62107,\ldots,91233)$
:	:
$u_i$	$X_i$
:	:
zack_tayland	$(1009, 23471, \dots, 47623)$
zoom42	$(63, 51234, \ldots, 72382)$

#### Honeychecker

- Store the correct indexes of each account
- Communicates with the main server through secure channel in an authenticated manner
- The honeychecker executes two commands
- Set: <c<sub>i</sub>, u<sub>i</sub> >
  - Sets correct password index c<sub>i</sub> for the user u<sub>i</sub>
- Check: <u<sub>i</sub>, j>
  - Checks whether c<sub>i</sub> for u<sub>i</sub> is equal to given j
  - Returns the result and if equality does not hold, notifies system a honeyword situation

#### Login process

- Need to check whether the entered password, g, is correct for the corresponding username u<sub>i</sub>
- First the X<sub>i</sub> of the corresponding u<sub>i</sub> is attained from the F1 file
- The hash values stored in F2 file for the respective indices in X<sub>i</sub> are compared with H(g) to find a match
- If a match is not obtained, then it means that g is neither the correct password, nor one of the honeywords, i.e., login fails
- If H(g) is found in the list, then the main server checks whether the account is a honeypot

- If it is a honeypot, then it follows a predefined security policy against the password disclosure scenario
- If, however, H(g) is in the list and it is not a honeypot, the corresponding j from X<sub>i</sub> is delivered to honeychecker with username as < u<sub>i</sub>, j > to verify it is the correct index
- Honeychecker controls whether j=c<sub>i</sub> and returns the result to the main server
- If it is not equal, then it assured that the proffered password is a honeyword and adequate actions should be taken depending on the policy
- Otherwise, login is successful

#### Assumptions

- We suppose that the adversary can invert most or many of the password hashes in file F2
- If user hits a password of another account in the system and the same user hits this situation more than once (trying with other passwords in F2), the system should turn on additional logging of the user's activities to detect a possible DoS attack and to attribute the adversary, besides the incorrect login attempt case proceeds as usual.

#### Assumptions (2)

- If a password, whose hash value is in the S<sub>H</sub> of the F<sub>2</sub>, is entered in wrong login attempts for more than once, the system should take actions against a possible DoS alarm
- In order to increase the number of unique passwords in the system, i.e., reduce common passwords, users should be forced to adhere to a password-composition policy

#### Assumptions (3)

- A username should not be correlated with its password
- To avoid occurrence of a high number of common passwords in the system, the user should be driven to choose another password when the created password is in the list of 1,000 most common passwords

#### **DoS Attack**

 Adversary has knowledge m + 1 username and respective passwords in the system

```
- as (< u_a, p_a>, ..., < u_{a+m}, p_{a+m}>)
```

- Create m accounts with the same password as
   p<sub>7</sub>
- If  $p_z$  is assigned by the system as a honeyword, then the adversary mounts a DoS attack by entering with the system  $\langle u_y, p_z \rangle$  pair

#### DoS Attack Analysis

- Let  $Pr(p_z \in W_y)$  denote the probability that  $p_z$  is assigned as one of the honeywords for  $u_v$
- It is also the success probability of the adversary for DoS attack

$$\Pr(p_z \in W_y) = 1 - \left(\frac{N-m}{N}\right)^k$$
.

#### DoS Attack Analysis

- If N = 1,000,000, k = 20 and m = 100,
  - then adversary succeeds in realizing the described attack with a probability of 0.002
- If N = 1,000, k = 20 and m = 10,
  - then adversary succeeds in realizing the described attack with a probability of 0.18

The success of the adversary directly depends on (m/N)

#### Password guessing

- If the adversary randomly picks an account from the list in F1 and then tries to login with a guessed password, then her success will depend on
  - Firstly, the selected account is not a honeypot (decoy) account
  - Secondly, guessing the correct password p<sub>i</sub> out of k sweetwords

- Let Pro(success)
   represents the probability
   that the adversary makes
   a correct guess for a
   randomly picked
   username
- $Prob(success) = \frac{N-T}{N} \cdot \frac{1}{k}$ 
  - Where T is the no. of honeypot accounts

A convenient choice for T could be  $N^{1/2}$  For k = 20 and N = 1,000,000, she picks the correct password  $p_i$  with 5% probability

#### **Storage Cost**

- A typical password file system requires
  - hN plus storage for usernames,
  - where N number of users in the system
  - h denotes length of password hash in bytes

- Honeyword-based system requires khN storage,
  - where k the number of the sweetwords assigned to each account

#### Gain in storage cost

 If each index requires 4 bytes and the storage cost becomes:

$$\square$$
4kN + hN + 4N

Gain in storage cost compared to the original scheme

$$\square \frac{4kN+hN+4N}{khN} = \frac{4k+h+4}{kh}$$
